APPLICATION FOR LETTERS PATENT

Intelligent Message Deletion

Inventor(s):
James Mason Boswell
Jeffrey L. Allen

ATTORNEY'S DOCKET NO. MS1-1912US

1 **TECHNICAL FIELD**

2 This invention relates to messaging and data communications, and more
3 particularly to intelligent message deletion.
4

5 **BACKGROUND**

6 It is frequently desirable for the users of current computing devices to
7 communicate with one another. For example, users may desire to send short
8 communications or messages to one another over the Internet. The users may use
9 these messages to communicate any of a variety of information, such as details
10 about their day, questions about homework, details about boyfriends/girlfriends,
11 information regarding computer games, just to chat, etc. It is also often desirable
12 to allow other entities, such as publishers of applications being used by the users,
13 or administrators of systems or services being used by the users, to communicate
14 with the users. For example, a publisher of an application may desire to send a
15 short communication or message to the users of the application about a new
16 version of the application that will soon be available.

17 With some devices, such as desktop computers, users can manage the
18 messages they receive fairly easily because of the input and output components
19 associated with those devices. For example, desktop computers typically have a
20 cursor control device (e.g., a mouse) and a keyboard that allow the user to easily
21 operate the computer's user interface and easily input a wide variety of
22 information in different manners (e.g., by point and click with the cursor control
23 device, by typing commands on the keyboard, etc.).
24
25

1 With other devices, however, it is more difficult for users to manage the
2 messages they receive. Some of these devices, such as game consoles, have a
3 more restricted user input mechanism, such as a game controller which may have a
4 few buttons, triggers, and/or joysticks to allow user input of information. With
5 such a restricted user input mechanism, managing received messages can be
6 cumbersome for the user. Additionally, some of these devices, such as game
7 consoles, typically display messages on a display device (such as a television) that
8 makes it difficult to read messages if too many messages are displayed at the same
9 time. These problems are only exacerbated as the number of messages received
10 by the user increases. Thus, it would be beneficial to have a way to reduce the
11 burden on the user of managing messages they receive.

12 13 SUMMARY

14 Intelligent message deletion is described herein.

15 In accordance with certain aspects of the intelligent message deletion, a
16 system includes a memory and an intelligent deletion module. The memory stores
17 a message queue, and the intelligent message deletion module adds a newly
18 received message to the message queue and deletes a previously received message
19 from the message queue based at least in part on an identity of a sender of the
20 newly received message.

21 In accordance with certain aspects of the intelligent message deletion, an
22 identification is made as to whether a message queue for a targeted recipient of a
23 new message has more than a threshold number of messages. If the queue does
24 not have more than the threshold number of messages then the new message is
25

1 added to the message queue. However, if the queue does have more than the
2 threshold number of messages, then a determination is made, based on a sender of
3 the new message, of one of the messages in the message queue to delete from the
4 message queue, that one message is deleted from the message queue, and the new
5 message is added to the message queue.

6 7 **BRIEF DESCRIPTION OF THE DRAWINGS**

8 The same numbers are used throughout the document to reference like
9 components and/or features.

10 Fig. 1 is a block diagram of an example environment implementing the
11 intelligent message deletion described herein.

12 Fig. 2 is a flowchart illustrating an example process for adding messages to
13 and intelligently deleting messages from a message queue.

14 Fig. 3 is a flowchart illustrating another example process for adding
15 messages to and intelligently deleting messages from a message queue.

16 Fig. 4 illustrates an example format for a message.

17 Fig. 5 illustrates an example of a general computer environment which can
18 be used to implement the techniques described herein.

19 20 **DETAILED DESCRIPTION**

21 Intelligent message deletion is described herein. Messages can be
22 communicated among various users of client devices. A message queue is
23 maintained for each user, and a limit is imposed on the number of messages that
24 can be in the message queue at any one time. When a new message is received for
25

1 the user and his or her message queue is at its limit, the intelligent message
2 deletion is used to determine which message in his or her message queue is to be
3 deleted in order to make room for the new message.

4 Fig. 1 is a block diagram of an example environment 100 implementing the
5 intelligent message deletion described herein. Multiple client devices 102(1), . . . ,
6 102(n) are coupled to a service 104 having a messaging component 106 to support
7 sending messages among the client devices 102. The couplings between devices
8 102 and service 104 can be any of a variety of couplings allowing communication
9 between system 104 and each of devices 102, including wired and/or wireless
10 couplings. In one implementation, the coupling includes the Internet, and may
11 also optionally include one or more other networks (e.g., a local area network
12 (LAN) or wide area network (WAN)).

13 Client devices 102 can take any of a variety of different forms, including
14 game consoles (such as the Xbox® video game system available from Microsoft
15 Corporation of Redmond, Washington), handheld or portable computing devices,
16 cellular telephones, personal digital assistants (PDAs), and so forth. Service 104
17 can be one or more computing devices that allow client devices 102 to
18 communicate with one another, as well as support storage of various information
19 for the client devices 102. In certain embodiments, service 104 is an online
20 gaming service (such as the Xbox Live™ online game service, access to which is
21 offered by Microsoft Corporation) that allows users of the client devices 102 to
22 play games against one another even though the client devices 102 are located in
23 physically different areas.

1 Messaging component 106 of service 104 allows the client devices 102 to
2 send messages to one another. Service 104 is typically the intermediary through
3 which the messages are sent, although alternatively messages may be sent directly
4 between client devices 102 without passing through service 104. The types of
5 messages which can be sent can vary, based on the desires of the users of the
6 client devices 102 as well as the message types supported by different applications
7 that may be running on client devices 102. In certain embodiments, different
8 applications can support different types of messages, and may even define their
9 own message types. Examples of types of messages which may be sent by users
10 include requests/acceptances to join a particular game or tournament being played
11 or about to be played, requests/acceptances to join a team of users,
12 requests/acceptances to create a friend relationship with another user (e.g.,
13 allowing the users to be notified when each other are signed on, or reserve spots in
14 games for the other users), reminders of upcoming games and/or tournaments,
15 personal notes or messages, and so forth. The messages can be sent by users from
16 within a particular application or title (e.g., whatever game the user is playing), or
17 alternatively from another process or component (e.g., a process or component
18 dedicated to messaging functionality).

19 Each user of a client device 102 has an associated user message queue 108.
20 In certain embodiments, each user of a client device 102 (and a client device 102
21 may have multiple users) has an account on service 104, and this account has an
22 associated message queue. Messages that are received at service 104 targeting a
23 particular other user (also referred to herein as the targeted recipient or receiver)
24 are placed into that particular other user's queue by messaging component 106.
25

1 Each user's message queue 108 includes zero or more messages (or
2 identifiers of messages) that are ready to be delivered to that user. Message
3 queues 108 can be implemented in any of a variety of manners using any of a
4 variety of different data structures that allow the zero or more messages that are
5 ready to be delivered to the users to be identified. In certain embodiments, the
6 messages are a fixed size, but can reference extensions that are stored in message
7 storage 112. Such an arrangement allows the storage requirements for messaging
8 component 106 to remain smaller, while still allowing large messages to be sent
9 by the users (with the data for such large messages being stored in message
10 storage 112). In alternate embodiments, such a separate message storage 112 need
11 not be used.

12 The quantity or number of messages that can be included in each user's
13 message queue 108 is limited. When a new message is received by service 104
14 targeting a particular user, and that user's message queue is already at its limit,
15 then one of the messages already in the user's message queue is deleted.
16 Messaging component 106 includes an intelligent message deletion module 110
17 that determines, based on various criteria, which message currently in the user's
18 message queue is to be deleted to make room for the new message. These criteria
19 and the intelligent message deletion are discussed in more detail below. Thus,
20 rather than rejecting the new message (and possibly notifying the sender of the
21 message that the recipient's queue is full), service 104 allows the new message to
22 be received and added to the queue, but selects one of the messages already in the
23 user's message queue to be deleted so that the message queue limit is not
24 exceeded.

1 Messages may be sent to users of client devices 102 when the users are
2 logged in to their account on service 104, or alternatively when the users are not
3 logged in to their account on service 104. If a message is sent to a user that is not
4 logged in to service 104, then the message is maintained at service 104 in the
5 user's message queue 108 until the user logs in to his or her account or
6 alternatively until the message is deleted from the user's message queue 108 (e.g.,
7 deleted by intelligent message deletion module 110 to make room for a new
8 message, or deleted because some period of time has elapsed (e.g., the message
9 has expired)).

10 In addition to users sending messages, other entities may also send
11 messages to users. One such entity is a system administrator of service 104 or an
12 application running at service 104. For example, such a system administrator or
13 application may send a message notifying a user(s) that his or her subscription to
14 service 104 is about to expire, that service 104 may be unavailable for a period of
15 time for maintenance, explaining new features or functionality that will be
16 available to the user(s) from service 104, and so forth. Another such entity is a
17 publisher of an application. For example, such a publisher may send a message
18 notifying a user(s) of an upcoming tournament or contest for the application (e.g.,
19 if the application is a game), of a new version of the application that is or soon will
20 be available, of other applications available from that publisher, and so forth. Yet
21 another such entity is an application itself. For example, an application running on
22 a client device 102 may send, on behalf of a user of the client device, a message to
23 other users notifying the other users of something that happened during running of
24 the game (e.g., a particular maneuver that occurred, or a particular result such as
25

1 being shot down in an aerial combat game), or of other information pertaining to
2 the application (e.g., statistics regarding a user's playing of a game application).

3 Typically, message queues 108 are associated with particular users rather
4 than particular client devices 102. This allows users to receive their messages
5 regardless of which client device 102 they are using. For example, a user may
6 have an account on service 104 and log in to the account using a client device 102
7 at a friend's house, allowing the user to receive messages that target him or her
8 while using the client device 102 at his or her friend's house. In alternate
9 embodiments, message queues 108 may be associated with particular client
10 devices 102 rather than particular users.

11 Messages targeting a user of a client device 102 can be retrieved (e.g., from
12 service 108) and played back (e.g., visually or audibly) by the user in a variety of
13 different manners. In certain embodiments, the user is given an indication such as
14 a flashing icon at the client device 102 he or she is using that a message is
15 available. The client device 102 then retrieves the message from service 104 when
16 the user indicates he or she is ready to play back the message. In certain other
17 embodiments, the message is automatically played back to the user without the
18 user having to request that it be played back.

19 Additionally, in some embodiments messages can be played back by the
20 user of a client device 102 from whatever application is currently running at client
21 device 102. For example, if the user is playing an aerial combat game, then the
22 game can be paused and the game can control playback of messages to the user.
23 In some implementations, only messages from the same game title can be played
24 back by that game title. For example, if the user is playing an aerial combat game,
25

1 any messages for the user that are from the same aerial combat game can be
2 played back to the user, whereas messages from other games (e.g., a car racing
3 game, a football game, a basketball game, etc.) are not played back by the aerial
4 combat game.

5 Alternatively, in other embodiments messages can be played back by the
6 user of a client device 102 from a process or component on the client device
7 dedicated to messaging functionality. For example, the user may be able to begin
8 a “messaging” application or “mail” application, allowing the user to play back
9 messages targeting him or her.

10 Furthermore, in addition to message playback, in some embodiments the
11 user of client device 102 is able to further manage his or her messages. For
12 example, the user may be able to select messages for deletion, select messages to
13 be saved, identify how long messages should be saved, and so forth. In other
14 embodiments, such additional management may be more restricted or nonexistent.
15 For example, a message may be automatically deleted by messaging component
16 106 as soon as the user has played back the message (the user would not be
17 allowed to save the message for later viewing).

18 Although illustrated as a centralized service architecture in Fig. 1, the
19 messaging between client devices may use different architectures. For example, in
20 certain embodiments message queues may be implemented on the individual client
21 devices 102 rather than on service 104. In such embodiments, the client devices
22 102 could maintain, for example, an outbound queue and an inbound queue.
23 When a user of a client device 102 sends a message, the message is placed in an
24 outbound queue of that client device and stays there until the targeted recipient of
25

1 the message is logged in to his or her account on service 104. When both the
2 sender and the recipient are logged in to their accounts on service 104, the
3 message is sent from the outbound queue of the sender to the inbound queue of the
4 recipient. Intelligent message deletion module 110 would also be implemented on
5 the client devices 102. For example, when a new message is received at a client
6 device, the client device uses its intelligent message deletion module as
7 appropriate to delete a message from its inbound queue so that the number of
8 messages in the inbound queue do not exceed a queue limit. In some
9 implementations, such messages may be sent directly between the client devices
10 102 rather than being sent by way of service 104 as illustrated in Fig. 1.

11 By way of another example, in other embodiments user message queues
12 108 are maintained at service 104 as illustrated in Fig. 1, but the intelligent
13 message deletion module 110 is implemented in the client devices 102. In such
14 embodiments, the client devices 102 make the determination as to which messages
15 are to be deleted from the queues maintained on service 104. For example, the
16 client device 102 being used by a targeted user of a message (or alternatively some
17 other client device, such as the client device 102 of the sender of the message, or
18 some other client device 102 with available bandwidth to make the determination)
19 determines which message should be deleted from the targeted user's message
20 queue on service 104 so that the message queue limit is not exceeded.

21 Fig. 2 is a flowchart illustrating an example process 150 for adding
22 messages to and intelligently deleting messages from a message queue. Process
23 150 is implemented by messaging component 106 of Fig. 1, and at least a portion
24 (e.g., acts 160-166) may be performed by intelligent message deletion module 110
25

1 of Fig. 1. Process 150 may be performed in software, hardware, firmware, or
2 combinations thereof. Process 150 is discussed with additional reference to
3 elements of Fig. 1.

4 Initially, a new message that targets a particular recipient is received (act
5 152), and the message queue associated with the targeted recipient is identified
6 (act 154). The message queue may be identified in any of a variety of different
7 manners. For example, in certain embodiments, service 104 may maintain a
8 mapping of user identifiers to particular message queues 108. When the new
9 message is received, the targeted recipient is identified in the new message by his
10 or her user identifier, and service 108 uses the mapping to identify the message
11 queue 108 associated with that targeted recipient.

12 A check is then made as to whether the message queue associated with the
13 targeted recipient is full (act 156). How many messages can be stored in the
14 message queue is restricted. In certain embodiments, the message queue is
15 restricted to holding no more than 100 messages, although alternatively this limit
16 or threshold may be more than or less than 100 messages. If the message queue is
17 not full, then the new message received in act 152 is added to the message queue
18 (act 158). In situations where the message queue is not full, no messages need to
19 be deleted from the message queue in order to make room for the new message, so
20 no messages are deleted from the message queue.

21 However, if the message queue is full, then the sender of the new message
22 is identified (act 160). The new message includes one or more fields that identify
23 the user and/or application (also referred to as a title) that sent the message. This
24 field(s) is accessed in act 160 to identify the sender of the new message.
25

1 A check is then made, based on the sender identified in act 160, whether
2 one or more criteria regarding the message queue are satisfied (act 162). These
3 one or more criteria refer to how many messages having the same sender can be
4 kept in the message queue. In certain embodiments, one such criteria refers to
5 how many messages sent from the same application can be kept in the message
6 queue. If greater than a threshold number of messages from the same application
7 are in the message queue, then the criteria is satisfied. This threshold number can
8 vary. In certain embodiments the threshold number is ten, although larger or
9 smaller threshold numbers may alternatively be used.

10 In certain embodiments, another such criteria refers to how many messages
11 sent from the same user can be kept in the message queue. If greater than a
12 threshold number of messages from the same user are in the message queue, then
13 the criteria is satisfied. This threshold number can vary. In certain embodiments
14 the threshold number is ten, although larger or smaller threshold numbers may
15 alternatively be used.

16 In some embodiments, the one or more criteria may refer to both how many
17 messages sent from the same application can be kept in the message queue and
18 how many messages sent from the same user can be kept in the message queue. In
19 other embodiments, the one or more criteria may refer to only one of how many
20 messages having the same sender can be kept in the message queue and how many
21 messages sent from the same user can be kept in the message queue.

22 If the one or more criteria are satisfied, then a determination is made, based
23 on the sender identified in act 160, which message is to be deleted from the
24 message queue in order to make room for the new message (act 164). In certain
25

1 embodiments, where the criteria refers to how many messages sent from the same
2 application can be kept in the message queue, the message to be deleted is the
3 oldest message in the message queue from the application identified in act 160.
4 Thus, in these embodiments, the oldest message in the message queue that is from
5 the same application as the application that sent the new message is deleted from
6 the queue.

7 In certain embodiments, where the criteria refers to how many messages
8 sent from the same user can be kept in the message queue, the message to be
9 deleted is the oldest message in the message queue from the user identified in act
10 160. Thus, in these embodiments, the oldest message in the message queue that is
11 from the same user as the user that sent the new message is deleted from the
12 queue.

13 However, if the one or more criteria regarding the message queue are not
14 satisfied in act 162, then the oldest message in the message queue is deleted from
15 the message queue (act 166). Act 166 is performed without regard for whether the
16 message to be deleted is from the same sender as the new message. The oldest
17 message can be determined in different manners, such as by analyzing the times
18 each of the messages was sent (e.g., as identified in a time sent field of the
19 messages) to determine which is oldest. Alternatively, the oldest message could
20 be determined in different manners, such as based on when the messages were
21 added to the message queue.

22 Regardless of which message is deleted from the message queue in act 164
23 or act 166, the new message is then added to the message queue (act 158).
24 Alternatively, rather than waiting for a message to be deleted from the message
25

1 queue, the new message may be added to the message queue prior to one of the
2 messages being deleted. Additionally, the message may be added to the message
3 queue prior to determining whether the message queue is full in act 156.

4 In process 150, the message deletion in acts 160-166 can be viewed as
5 intelligent due to the various criteria and intelligence relied on in determining
6 which message is to be deleted from the message queue. The process 150
7 employs more intelligence than simply always deleting the oldest message or
8 refusing to allow a new message to be added to the message queue. This provides
9 numerous benefits, including keeping newer messages in the user's message queue
10 so that if there is an extended period of time during which the user does not read
11 the messages in his or her message queue, when he or she does return to read those
12 messages he or she reads the more recent messages rather than old (and perhaps no
13 longer useful) messages.

14 Fig. 3 is a flowchart illustrating another example process 200 for adding
15 messages to and intelligently deleting messages from a message queue. Process
16 200 is implemented by messaging component 106 of Fig. 1, and at least a portion
17 (e.g., acts 210-222) may be performed by intelligent message deletion module 110
18 of Fig. 1. Process 200 may be performed in software, hardware, firmware, or
19 combinations thereof. Process 200 is discussed with additional reference to
20 elements of Fig. 1.

21 Initially, a new message that targets a particular recipient is received (act
22 202), and the message queue associated with the targeted recipient is identified
23 (act 204). Acts 202 and 204 are analogous to acts 152 and 154 of Fig. 2. As
24
25

1 discussed above with reference to Fig. 2, the message queue may be identified in
2 any of a variety of different manners.

3 A check is then made as to whether the message queue associated with the
4 targeted recipient is full (act 206). Act 206 is analogous to act 156 of Fig. 2. If
5 the message queue is not full, then the new message received in act 202 is added
6 to the message queue (act 208), analogous to act 158 of Fig. 2. In situations where
7 the message queue is not full, no messages need to be deleted from the message
8 queue in order to make room for the new message, so no messages are deleted
9 from the message queue.

10 However, if the message queue is full, then the title that sent the new
11 message is identified (act 210). The title that sent the new message refers to the
12 application (typically a game) running on the client device 102 that sends (or
13 originates) the message. The title itself may be responsible for communicating the
14 message to service 104, or alternatively some other application on the client
15 device may be responsible for communicating the message from the title to service
16 104. The new message includes one or more fields that identify the title that sent
17 the message. This field(s) is accessed in act 210 to identify the title that sent the
18 new message.

19 For entities other than an application running on a client device 102 that
20 may send a message, a title is optionally assigned to the entity. For example, there
21 may be a title that represents service 104 of Fig. 1, so all messages from an
22 administrator of service 104 are assigned that title. By way of another example, a
23 publisher of a title may send messages to users, and that title is assigned to those
24 messages from the publisher.
25

1 A check is then made as to whether a threshold number or quantity of
2 messages from the title identified in act 210 are already in the message queue (act
3 212). This threshold number can vary. In certain embodiments the threshold
4 number is ten, although larger or smaller threshold numbers may alternatively be
5 used. If the threshold number or quantity of messages from the title are already in
6 the message queue, then the oldest message in the message queue from the title
7 identified in act 210 is deleted from the message queue (act 214) and the new
8 message is added to the message queue (act 208).

9 Returning to act 212, if the threshold number or quantity of messages from
10 the title identified in act 210 are not already in the message queue, then the user
11 that sent the new message is identified (act 216). The new message includes one
12 or more fields that identify the user that sent the message. This field(s) is accessed
13 in act 216 to identify the user that sent the new message. The user that sent the
14 new message refers to the user of the client device 102 when the message was sent
15 (e.g., as identified by an account name or id used by the user to log in to service
16 104 of Fig. 1), or an identifier of a non-user entity (e.g., a publisher, system
17 administrator of service 104, etc.). In some situations, messages may be
18 automatically initiated and sent by a title on behalf of a user. For example, an
19 aerial combat game being played by a particular user may automatically generate
20 messages to other users when that particular user is shot down. In such situations,
21 even though the message is not initiated by the user, because the message was
22 initiated on behalf of the user the message identifies the user as the user that sent
23 the message.
24
25

1 A check is then made as to whether a threshold number or quantity of
2 messages from the user identified in act 216 are already in the message queue (act
3 218). This threshold number can vary. In certain embodiments the threshold
4 number is ten, although larger or smaller threshold numbers may alternatively be
5 used. If the threshold number or quantity of messages from the user are already in
6 the message queue, then the oldest message in the message queue from the user
7 identified in act 216 is deleted from the message queue (act 220) and the new
8 message is added to the message queue (act 208).

9 However, if the threshold number or quantity of messages from the user
10 identified in act 216 are not already in the message queue, then the oldest message
11 in the message queue is deleted from the message queue (act 222). Analogous to
12 act 166 of Fig. 2, the oldest message can be determined in different manners, such
13 as by analyzing the times each of the messages in the queue was sent, or based on
14 when the messages were added to the queue.

15 In process 200, when the message queue is full the new message is
16 described as being added to the message queue after a message is deleted from the
17 message queue. Alternatively, rather than waiting for a message to be deleted
18 from the message queue, the new message may be added to the message queue
19 prior to one of the messages being deleted. Additionally, the message may be
20 added to the message queue prior to determining whether the message queue is
21 full in act 206.

22 In process 200, the message deletion in acts 210-222 can be viewed as
23 intelligent due to the various criteria and intelligence relied on in determining
24 which message is to be deleted from the message queue. The process 200
25

1 employs more intelligence than simply always deleting the oldest message or
2 refusing to allow a new message to be added to the message queue. This provides
3 numerous benefits, including keeping newer messages in the user's message queue
4 so that if there is an extended period of time during which the user does not read
5 the messages in his or her message queue, when he or she does return to read those
6 messages he or she reads the more recent messages rather than old (and perhaps no
7 longer useful) messages.

8 Referring back to Figs. 1, 2, and 3, by determining which message to delete
9 from the message queue to make room for a new message has the effect of
10 preventing a sender from filling up a user's message queue and forcing messages
11 from another sender out of the message queue. For example, if the same user were
12 to send 100 messages to a particular recipient user, the first ten messages from that
13 same user could cause messages from other users to be removed from the
14 recipient's message queue, but the next ninety messages would simply cause one
15 of the previous messages from that same user to be removed from the recipient's
16 message queue. By way of another example, if the same title were to send 100
17 messages to a particular recipient user, the first ten messages from that same title
18 could cause messages from other titles to be removed from the recipient's message
19 queue, but the next ninety messages would simply cause one of the previous
20 messages from that same title to be removed from the recipient's message queue.

21 It should also be noted that in certain situations the restriction on the size of
22 the message queue may be violated by service 104. For example, messages of
23 certain types or from certain senders (e.g., a system administrator) may not be
24 included in the number of messages in the message queue. So, if the message
25

1 queue were limited to 100 messages, and there were 97 messages in the queue that
2 were not from these certain senders or of these certain types, but there were five
3 messages in the queue that were from these certain senders or of these certain
4 types, then the message queue would not be full.

5 It should further be noted that certain messages may not be deleted
6 according to the intelligent message deletion processes discussed above. Certain
7 message types, messages from certain senders, or certain messages may not be
8 deleted by the intelligent message deletion processes discussed above. Which
9 messages are not to be deleted can be identified in different manners, such as by
10 setting a flag value in the message indicating the message is not to be deleted, or
11 having intelligent message deletion module 110 of Fig. 1 programmed or
12 configured so as not to delete messages of particular types or from particular
13 senders. For example, if process 150 or 200 determines that the oldest message in
14 the message queue is to be deleted, but the oldest message may not be deleted
15 because of the sender or type of the oldest message, then the oldest message that is
16 not of this type or from this sender is deleted. By way of another example, if
17 process 200 determines that there are more than the threshold number of messages
18 in the queue from this sender, but messages from this sender are not to be deleted,
19 then some other message in the message queue is deleted (e.g., the oldest message
20 in the message queue).

21 Fig. 4 illustrates an example format for a message. Any of a variety of
22 different formats of messages, including any of a variety of different information,
23 may be used with the intelligent message deletion discussed herein.
24
25

1 Fig. 4 illustrates an example message 250 having a meta data portion 252, a
2 body portion 254, and an optional attachment portion 256. Meta data portion 252
3 includes one or more fields describing various aspects of message 250, while body
4 portion 254 includes any additional content, such as text or voice content, for the
5 message. In certain embodiments, no such content need be included in body
6 portion 256, but rather all of the information necessary for the message is included
7 in meta data portion 252. For example, a message sent by a user to create a friend
8 relationship with another user may have all of the necessary information included
9 in meta data portion 252, so that no content need be included in body portion 254.

10 An attachment 256 may also be included as part of a message. In certain
11 embodiments, the size of meta data portion 252 and body portion 254 may be
12 limited (e.g., to 4,096 bytes). If a user's message includes content requiring
13 additional space, such as a voice attachment, the content (or at least part of the
14 content) is included in attachment portion 256.

15 A variety of different information can be included in the fields of meta data
16 portion 252. In certain embodiments, meta data portion 252 includes one or more
17 of the following fields: size, message ID, message type, sender ID, gamer tag,
18 recipient ID, time sent, expiration, message pointer, title ID, flags, language, and
19 region/country. These example fields are described in Table I below.

Table I

Field	Description
size	Total size of the message (e.g., in bytes), including the meta data portion, body portion, and attachment portion.
message ID	An identifier that uniquely identifies this message to the service (e.g., service 104 of Fig. 1).
message type	The type of the message.
sender ID	An identifier of the sender of the message. One or more special values (e.g., zero) are used to indicate a non-user sender (e.g., the system or a publisher).
gamer tag	User identifier to display to the recipient as the sender of the message.
recipient ID	An identifier of the targeted recipient of the message.
time sent	The time (and optionally date) the message was sent by the sender.
expiration	The date and/or time the message is to expire. May be a specific date and/or time (e.g., April 15 at 3:05pm), or a relative time (e.g., 30 days after being sent). Can be set by the sender's client device or service 104. Different message types (and even different messages of the same type) can optionally have different expirations, even if sent at the same (or approximately the same) time.
message pointer	A pointer to an attachment (e.g., attachment portion 256). May also optionally be used, for example, for voice attachments.
title ID	An identifier of the title from which the message was sent.
flags	Various flags that may be set for the message, such as whether the message is read/unread, whether the message has a voice attachment, whether the message has a text attachment, whether the message has a graphic attachment (e.g., a screenshot), and so forth.
language	An identifier of the language of the message (e.g., English, Japanese, French, Chinese, and so forth).
region/country	An identifier of the region or country that the sender of the message is located in.

It should be noted that, in addition to the processes 150 and 200 discussed above, other processes may also be used to delete messages from the message

1 queue. For example, intelligent message deletion module 110 (or alternatively
2 some other component of service 104 or messaging component 106) may monitor
3 the expiration fields of messages in the message queue and delete any message
4 from the message queue after its expiration date and/or time has passed. By way
5 of another example, intelligent message deletion module 110 (or alternatively
6 some other component of service 104 or messaging component 106) may impose a
7 general limit on how long messages can be kept in the message queue (this general
8 limit may optionally apply to those messages that are not to be deleted). In certain
9 embodiments, this general limit is 45 days, although greater or lesser durations
10 may alternatively be used. Additionally, different general limits may be used for
11 different types of messages. For example, the general limit for keeping requests to
12 join a particular game may be 24 hours, so such messages are deleted after 24
13 hours. By way of another example, the general limit for requesting to create a
14 friend relationship with another user may be 45 days, so such messages are deleted
15 after 45 days. These general limits may override any expiration dates or times
16 identified in the expiration field of the message, or alternatively these general
17 limits may be default values that are used only if the expiration field of the
18 message contains no expiration date or time.

19 Fig. 5 illustrates an example of a general computer environment 300, which
20 can be used to implement the techniques described herein. The computer
21 environment 300 is only one example of a computing environment and is not
22 intended to suggest any limitation as to the scope of use or functionality of the
23 computer and network architectures. Neither should the computer environment
24
25

1 300 be interpreted as having any dependency or requirement relating to any one or
2 combination of components illustrated in the example computer environment 300.

3 Computer environment 300 includes a general-purpose computing device in
4 the form of a computer 302. One or more computers 302 can be used to
5 implement, for example, service 104 of Fig. 1. The components of computer 302
6 can include, but are not limited to, one or more processors or processing units 304,
7 a system memory 306, and a system bus 308 that couples various system
8 components including the processor 304 to the system memory 306.

9 The system bus 308 represents one or more of any of several types of bus
10 structures, including a memory bus or memory controller, a peripheral bus, an
11 accelerated graphics port, and a processor or local bus using any of a variety of
12 bus architectures. By way of example, such architectures can include an Industry
13 Standard Architecture (ISA) bus, a Micro Channel Architecture (MCA) bus, an
14 Enhanced ISA (EISA) bus, a Video Electronics Standards Association (VESA)
15 local bus, and a Peripheral Component Interconnects (PCI) bus also known as a
16 Mezzanine bus.

17 Computer 302 typically includes a variety of computer readable media.
18 Such media can be any available media that is accessible by computer 302 and
19 includes both volatile and non-volatile media, removable and non-removable
20 media.

21 The system memory 306 includes computer readable media in the form of
22 volatile memory, such as random access memory (RAM) 310, and/or non-volatile
23 memory, such as read only memory (ROM) 312. A basic input/output system
24 (BIOS) 314, containing the basic routines that help to transfer information
25

1 between elements within computer 302, such as during start-up, is stored in ROM
2 312. RAM 310 typically contains data and/or program modules that are
3 immediately accessible to and/or presently operated on by the processing unit 304.

4 Computer 302 may also include other removable/non-removable,
5 volatile/non-volatile computer storage media. By way of example, Fig. 5
6 illustrates a hard disk drive 316 for reading from and writing to a non-removable,
7 non-volatile magnetic media (not shown), a magnetic disk drive 318 for reading
8 from and writing to a removable, non-volatile magnetic disk 320 (e.g., a “floppy
9 disk”), and an optical disk drive 322 for reading from and/or writing to a
10 removable, non-volatile optical disk 324 such as a CD-ROM, DVD-ROM, or other
11 optical media. The hard disk drive 316, magnetic disk drive 318, and optical disk
12 drive 322 are each connected to the system bus 308 by one or more data media
13 interfaces 326. Alternatively, the hard disk drive 316, magnetic disk drive 318,
14 and optical disk drive 322 can be connected to the system bus 308 by one or more
15 interfaces (not shown).

16 The disk drives and their associated computer-readable media provide non-
17 volatile storage of computer readable instructions, data structures, program
18 modules, and other data for computer 302. Although the example illustrates a hard
19 disk 316, a removable magnetic disk 320, and a removable optical disk 324, it is to
20 be appreciated that other types of computer readable media which can store data
21 that is accessible by a computer, such as magnetic cassettes or other magnetic
22 storage devices, flash memory cards, CD-ROM, digital versatile disks (DVD) or
23 other optical storage, random access memories (RAM), read only memories
24 (ROM), electrically erasable programmable read-only memory (EEPROM), and
25

1 the like, can also be utilized to implement the example computing system and
2 environment.

3 Any number of program modules can be stored on the hard disk 316,
4 magnetic disk 320, optical disk 324, ROM 312, and/or RAM 310, including by
5 way of example, an operating system 326, one or more application programs 328,
6 other program modules 330, and program data 332. Each of such operating
7 system 326, one or more application programs 328, other program modules 330,
8 and program data 332 (or some combination thereof) may implement all or part of
9 the resident components that support the distributed file system.

10 A user can enter commands and information into computer 302 via input
11 devices such as a keyboard 334 and a pointing device 336 (e.g., a "mouse").
12 Other input devices 338 (not shown specifically) may include a microphone,
13 joystick, game pad, satellite dish, serial port, scanner, and/or the like. These and
14 other input devices are connected to the processing unit 304 via input/output
15 interfaces 340 that are coupled to the system bus 308, but may be connected by
16 other interface and bus structures, such as a parallel port, game port, or a universal
17 serial bus (USB).

18 A monitor 342 or other type of display device can also be connected to the
19 system bus 308 via an interface, such as a video adapter 344. In addition to the
20 monitor 342, other output peripheral devices can include components such as
21 speakers (not shown) and a printer 346 which can be connected to computer 302
22 via the input/output interfaces 340.

23 Computer 302 can operate in a networked environment using logical
24 connections to one or more remote computers, such as a remote computing device
25

1 348. By way of example, the remote computing device 348 can be a personal
2 computer, portable computer, a server, a router, a network computer, a peer device
3 or other common network node, and the like. The remote computing device 348 is
4 illustrated as a portable computer that can include many or all of the elements and
5 features described herein relative to computer 302.

6 Logical connections between computer 302 and the remote computer 348
7 are depicted as a local area network (LAN) 350 and a general wide area network
8 (WAN) 352. Such networking environments are commonplace in offices,
9 enterprise-wide computer networks, intranets, and the Internet.

10 When implemented in a LAN networking environment, the computer 302 is
11 connected to a local network 350 via a network interface or adapter 354. When
12 implemented in a WAN networking environment, the computer 302 typically
13 includes a modem 356 or other means for establishing communications over the
14 wide network 352. The modem 356, which can be internal or external to computer
15 302, can be connected to the system bus 308 via the input/output interfaces 340 or
16 other appropriate mechanisms. It is to be appreciated that the illustrated network
17 connections are examples and that other means of establishing communication
18 link(s) between the computers 302 and 348 can be employed.

19 In a networked environment, such as that illustrated with computing
20 environment 300, program modules depicted relative to the computer 302, or
21 portions thereof, may be stored in a remote memory storage device. By way of
22 example, remote application programs 358 reside on a memory device of remote
23 computer 348. For purposes of illustration, application programs and other
24 executable program components such as the operating system are illustrated herein
25

1 as discrete blocks, although it is recognized that such programs and components
2 reside at various times in different storage components of the computing device
3 302, and are executed by the data processor(s) of the computer.

4 Various modules and techniques may be described herein in the general
5 context of computer-executable instructions, such as program modules, executed
6 by one or more computers or other devices. Generally, program modules include
7 routines, programs, objects, components, data structures, etc. that perform
8 particular tasks or implement particular abstract data types. Typically, the
9 functionality of the program modules may be combined or distributed as desired in
10 various embodiments.

11 An implementation of these modules and techniques may be stored on or
12 transmitted across some form of computer readable media. Computer readable
13 media can be any available media that can be accessed by a computer. By way of
14 example, and not limitation, computer readable media may comprise "computer
15 storage media" and "communications media."

16 "Computer storage media" includes volatile and non-volatile, removable
17 and non-removable media implemented in any method or technology for storage
18 of information such as computer readable instructions, data structures, program
19 modules, or other data. Computer storage media includes, but is not limited to,
20 RAM, ROM, EEPROM, flash memory or other memory technology, CD-ROM,
21 digital versatile disks (DVD) or other optical storage, magnetic cassettes, magnetic
22 tape, magnetic disk storage or other magnetic storage devices, or any other
23 medium which can be used to store the desired information and which can be
24 accessed by a computer.

1 “Communication media” typically embodies computer readable
2 instructions, data structures, program modules, or other data in a modulated data
3 signal, such as carrier wave or other transport mechanism. Communication media
4 also includes any information delivery media. The term “modulated data signal”
5 means a signal that has one or more of its characteristics set or changed in such a
6 manner as to encode information in the signal. By way of example, and not
7 limitation, communication media includes wired media such as a wired network or
8 direct-wired connection, and wireless media such as acoustic, RF, infrared, and
9 other wireless media. Combinations of any of the above are also included within
10 the scope of computer readable media.

11 One or more flowcharts are described herein and illustrated in the
12 accompanying Figures. The ordering of acts in these flowchart(s) are examples
13 only – these orderings can be changed so that the acts are performed in different
14 orders and/or concurrently.

15 Although the description above uses language that is specific to structural
16 features and/or methodological acts, it is to be understood that the invention
17 defined in the appended claims is not limited to the specific features or acts
18 described. Rather, the specific features and acts are disclosed as exemplary forms
19 of implementing the invention.
